(54) Title: **TFIIB TRANSCRIPTION FACTOR FROM CANDIDA ALBICANS**

(57) Abstract

The invention encompasses a novel transcription factor from *Candida albicans*, TFIIB, a nucleic acid sequence encoding TFIIB, and methods of screening for inhibitors of *Candida albicans* growth by targeting TFIIB.

TFIIB TRANSCRIPTION FACTOR FROM CANDIDA ALBICANS

ABSTRACT OF THE DISCLOSURE

15 The invention encompasses a novel transcription factor from *Candida albicans*, TFIIB, a nucleic acid sequence encoding TFIIB, and methods of screening for inhibitors of *Candida albicans* growth by targeting TFIIB.

20 The invention relates in general to transcription factors and to methods for screening for antifungal agents.

 The invention was made in part using government funds, NIH grant no. GM46498, and therefore the U.S. government has certain rights in the invention.

BACKGROUND OF THE INVENTION

25 The yeast *Candida albicans* (*C. albicans*) is one of the most pervasive fungal pathogens in humans. It has the capacity to opportunistically infect a diverse spectrum of compromised hosts, and to invade many diverse tissues in the human body. It can in many instances evade antibiotic treatment and the immune system.

30 Although *Candida albicans* is a member of the normal flora of the mucous membranes in the respiratory, gastrointestinal, and female genital tracts, in such locations, it may gain dominance and be associated with pathologic conditions. Sometimes it produces progressive systemic disease in debilitated or immunosuppressed patients, particularly if cell-mediated immunity is impaired. Sepsis may occur in patients with compromised cellular immunity, e.g., those undergoing cancer chemotherapy or those with

lymphoma, AIDS, or other conditions. *Candida* may produce bloodstream invasion, thrombophlebitis, endocarditis, or infection of the eyes and virtually any organ or tissue when introduced intravenously, e.g., via tubing, needles, narcotics abuse, etc.

Candida albicans has been shown to be diploid with balanced lethals, 5 and therefore probably does not go through a sexual phase or meiotic cycle. This yeast appears to be able to spontaneously and reversibly switch at high frequency between at least seven general phenotypes. Switching has been shown to occur not only in standard laboratory strains, but also in strains isolated from the mouths of healthy individuals.

10 Nystatin, ketoconazole, and amphotericin B are drugs which have been used to treat oral and systemic *Candida* infections. However, orally administered nystatin is limited to treatment within the gut and is not applicable to systemic treatment. Some systemic infections are susceptible to treatment with ketoconazole or amphotericin B, but these drugs may not be effective in such treatment unless 15 combined with additional drugs. Amphotericin B has a relatively narrow therapeutic index and numerous undesirable side effects and toxicities occur even at therapeutic concentrations. While ketoconazole and other azole antifungals exhibit significantly lower toxicity, their mechanism of action, inactivation of cytochrome P₄₅₀ prosthetic group in certain enzymes, some of which are found in humans, precludes use in 20 patients that are simultaneously receiving other drugs that are metabolized by the body's cytochrome P₄₅₀ enzymes. In addition, resistance to these compounds is emerging and may pose a serious problem in the future.

There is a need in the art for an effective treatment of opportunistic infections caused by *Candida albicans*. Therefore, one object of the invention is to 25 provide screening assays for identifying potential inhibitors of *Candida albicans* growth. Another object of the invention is to provide screening assays and to identify potential inhibitors of *Candida albicans* growth that are based on inhibition of transcription in this organism.

Synthesis of mRNA in eukaryotes requires RNA polymerase II and 30 accessory transcription factors, some of which are general and act at most, if not all, promoters, and others of which confer specificity and control. Five general factors, a, b, d, e, and g, have been purified to homogeneity from the yeast *S. cerevisiae*, and have been identified as counterparts of human or rat factors, TFIIE, TFIIH, TFIID,

TFIIB and TFIIF, respectively. These factors assemble at a promoter in a complex with RNA polymerase II to initiate transcription. Binding studies have shown that the order of assembly of the initiation complex on promoter DNA begins with factor d (TFIID), is followed by factor e (TFIIB), and then by polymerase and the remaining 5 factors. Factors b (TFIIB), e (TFIIB) and g (TFIIF), however, bind directly to polymerase II, and as many as four of the five factors may assemble with the polymerase in a holoenzyme before promoter binding. The functional significance of interactions revealed by binding studies is not clear in that only a few percent of initiation complexes may give rise to transcripts.

Many aspects of transcription by RNA polymerase II are conserved between yeast and higher eukaryotes. For example, there is extensive amino acid sequence similarity among the largest subunits of the yeast, Drosophila and mammalian polymerase. Other components of the transcription apparatus, such as TATA-binding and enhancer binding factors, are in some instances interchangeable between yeast and 15 mammalian *in vitro* binding or transcription systems. There are, nonetheless, significant differences between the two systems. TATA elements are located from 40 to 120 or more base pairs upstream of the initiation site of an *S. cerevisiae* promoter, and where these elements occur, they are required for gene expression. The fact that *C. albicans* genes function in *S. cerevisiae* suggests that it also uses the 40 to 120 20 base pair spacing between the TATA element and initiation site. In contrast, mammalian (as well as *S. pombe*) TATA elements and transcription start sites are only 25 to 30 bp apart, and deletion of a TATA element does not always reduce the frequency of transcription initiation, although it may alter the initiation site. There are also varying degrees of homology between transcription factor sequences from 25 yeast and mammalian sources. Human and *S. cerevisiae* TFIIB's have 50-60% amino acid sequence identity, and also are not species interchangeable in supporting cell growth. Some of the multisubunit factors, such as RNA polymerase II, TFIIF and TFIID, contain different numbers of subunits in humans and yeast. The molecular weights of corresponding polypeptides differ in humans and yeast with sequences being 30 present in a given yeast factor that are not present in its human counterpart, and vice versa.

Operative substitution of the same transcription factor in transcription systems of different yeast strains is not predictable. This is true despite a high degree

of amino acid sequence identity among some transcription factors from different yeast strains. For example, the ability of a given transcription factor to support efficient and accurate transcription in a heterologous yeast strain is not predictable. Li et al. (1994, Science 263:805) tested the interchangeability of *S. cerevisiae* and *S. pombe* transcription factors in vitro, and report that many *S. cerevisiae* components cannot substitute individually for *S. pombe* transcription factors *a*, *e*, or RNA polymerase II, but combinations of these components were effective. In one instance, active transcription could not be reconstituted when *S. cerevisiae*-derived TFIIB was the sole substitution into a TFIIB-depleted set of factors from *S. pombe*. A TFIIB-RNA polymerase II combination from *S. cerevisiae* was able to substitute, indicating that the functional interaction of these two components is not only important, but also that the activity may be dependent on species-specific determinants that cannot be complemented by either component derived from a different organism. The unpredictability in making substitutions of a given factor among different yeast strains is also evident in that such substitutions are not reciprocal; that is, substitutions of *S. pombe* fractions into an *S. cerevisiae* transcription system are less effective than the reverse substitutions (Li et al., supra).

The yeast *Candida albicans* differs from most yeast strains in that it does not use the same genetic code that most organisms, whether mammalian or yeast, utilize. Santos et al. (1995, Nucleic Acids Research, 23:1481) report that the codon CUG, which in the universal code is read as a leucine, is decoded as a serine in *Candida*. Therefore, any CUG codon that is decoded in *Candida albicans* as a serine, would be decoded as a leucine in the transformed *S. cerevisiae*. Any gene containing a CUG codon would therefore be translated as different amino acid sequences in *Candida albicans* and *S. cerevisiae*. Such mistranslation may produce an inactive protein, since the amino acids serine and leucine have markedly different chemical properties and serine is known to be an essential residue in the active site of some enzymes. Replacement of leucine by serine at CUG encoded residues is a serious problem in the use of many reporter systems (e.g., β -galactosidase, Chloramphenicol acetyltransferase, Flux) in *Candida albicans*. Previous experiments have shown that translation by *Candida* of CUG as serine instead of leucine often resulted in the production of inactive reporter proteins.

Another object of the invention is to provide an assay for screening for selective inhibition of Candida albicans growth and/or viability.

Yet another object of the invention is to provide a molecular target for inhibition of Candida albicans transcription or transcription initiation.

5

SUMMARY OF THE INVENTION

The invention encompasses a recombinant nucleic acid comprising a nucleic acid sequence encoding Candida albicans TFIIB.

10 The invention also encompasses a vector comprising a nucleic acid sequence encoding Candida albicans TFIIB, and a transformed host cell containing a nucleic acid sequence encoding Candida albicans TFIIB.

15 The invention also encompasses a recombinant polypeptide comprising Candida albicans TFIIB, and a fragment of Candida albicans TFIIB, the fragment being characterized in that it inhibits the biological activity of Candida albicans TFIIB in transcription initiation, or prevents the growth of Candida albicans.

The invention also encompasses a method for producing recombinant Candida albicans TFIIB, comprising culturing a host cell transformed with a nucleic acid encoding Candida albicans TFIIB under conditions sufficient to permit expression of the nucleic acid encoding Candida albicans TFIIB, and isolating Candida albicans TFIIB.

20 The invention also encompasses a screening method for identifying an inhibitor of Candida albicans growth, comprising detecting inhibition of mRNA transcription in an *in vitro* transcription assay comprising a DNA template, RNA polymerase II, recombinant Candida albicans TFIIB, and a candidate inhibitor, wherein production of an mRNA transcript complementary to the DNA template occurs in the absence of the candidate inhibitor. Preferably, the assay will also include *C. albicans* TBP.

25 The invention also encompasses a screening method for identifying an inhibitor of Candida albicans growth, comprising detecting in the presence of a candidate inhibitor inhibition of formation of a complex comprising a DNA template recombinant Candida albicans TFIIB and TBP, wherein in the absence of the candidate inhibitor, formation of the complex occurs.

The invention also encompasses a screening method for identifying an inhibitor of Candida albicans growth, comprising detecting in the presence of a candidate inhibitor inhibition of formation of a complex comprising Candida albicans TFIIB and Candida albicans TBP, wherein in the absence of the candidate inhibitor formation of the complex occurs. Preferably, the complex will include a DNA template.

The invention also encompasses a screening method for identifying an inhibitor of Candida albicans growth, comprising detecting in the presence of a candidate inhibitor inhibition of formation of a complex comprising RNA polymerase II, Candida albicans TBP, and Candida albicans TFIIB, wherein in the absence of the candidate inhibitor formation of the complex occurs. Preferably, the complex may also include a DNA template; and RNA polymerase II from *C. albicans*.

In the above-described screening methods, detection may be performed in the presence of a plurality of candidate inhibitors. In screening methods of the invention which involve screening of a plurality of candidate inhibitors, the plurality of inhibitors may be screened together in a single assay or individually using multiple simultaneous individual detecting steps.

The invention also encompasses a method of preventing Candida albicans growth in culture, comprising contacting the culture with an inhibitor that selectively inhibits the biological activity of Candida albicans TFIIB.

The invention also encompasses a method of preventing Candida albicans growth in a mammal, comprising contacting the mammal with an inhibitor that selectively inhibits the biological activity of Candida albicans TFIIB.

As used herein, "inhibition" refers to a reduction in the parameter being measured, whether it be Candida albicans growth or viability, Candida albicans TFIIB-mediated transcription, or formation of a Candida albicans TFIIB transcription complex. The amount of such reduction is measured relative to a standard (control). Because of the multiple interactions of Candida albicans TFIIB in transcription initiation, the target product for detection varies with respect to the particular screening assay employed. Three preferred detection products presented in this disclosure are; a) newly transcribed mRNA, b) a DNA-TFIIB complex, and c) a TBP-TFIIB-RNA polymerase complex. "Reduction" is defined herein as a decrease of at least 25% relative to a control, preferably of at least 50%, and most preferably of at least 75%.

As used herein, "growth" refers to the normal growth pattern of *Candida albicans*, i.e., to a cell doubling time of 60-90 minutes. "Viability" refers to the ability of *Candida albicans* to survive in culture for 48 hours.

"Biological activity" refers to the ability of TFIIB to form a transcription complex with a DNA template or other proteins of the transcription complex, or to interact with other transcription components so as to permit initiation of transcription.

"DNA template" refers to double stranded DNA and, where indicated by the particular binding assay to single stranded DNA, at least 10 nucleotides in length, that may be negatively supercoiled, possesses a promoter region, and contains a yeast TATA consensus region upstream of the promoter. DNA templates useful herein preferably contain a TATA sequence that is located from 40 to 120 or more base pairs upstream of the initiation site (distance measured from the first T of the TATA element to the 5'-most initiation site). An especially efficient DNA template for use in methods of the invention involving transcription is devoid of guanosine residues, and therefore a "G-minus" or "G-less" cassette is preferred (Sawdago and Roeder, 1985, PNAS 82:4394-4398).

"mRNA transcript" refers to a full-length transcript as well as to truncated transcripts, oligonucleotide transcripts and dinucleotide RNAs.

"Formation of a complex" refers to the binding of TFIIB to other transcription factors (i.e., protein-protein binding) as well as to binding of TFIIB to a DNA template; such binding will, of course, be a non-covalent association.

Other features and advantages of the invention will be apparent from the description, preferred embodiments thereof, the drawings, and from the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 presents the nucleotide and amino acid sequences of the *Candida albicans* transcription factor TBP.

Fig. 2 presents nucleotide and amino acid sequence of the *Candida albicans* transcription factor TFIIB.

30 DESCRIPTION

The invention is based on the discovery of a novel protein, *Candida albicans* TFIIB, and on the isolation of recombinant DNA encoding *Candida albicans* transcription factor TFIIB. Because TFIIB is essential for viability of the cell, a

compound that blocks the biological activity of the protein is expected to have fungicidal properties. Therefore, the invention is also based on the development of assays for screening from inhibitors of TFIIB.

5 Isolation and Characterization of the *Candida albicans* TBP and TFIIB Genes

Given the unpredictability with respect to operative substitutions of a given transcription factor among different yeast strains, one cannot assume that strategies for cloning of the gene encoding a given transcription factor which are based on factor function, such as genetic complementation, will work. Other cloning strategies, which
10 do not require functional complementation, such as those based on homology at the nucleic acid level, may be utilized in an attempt to circumvent a requirement for factor function. For example, Southern hybridization of specific sequences to a library carried
15 in *E. coli* and PCR amplification of potentially highly homologous regions of a gene are two strategies that have been successfully used to clone homologous genes from different organisms. To ascertain the likelihood of success of these or similar methods, we performed a Southern hybridization experiment where a radiolabeled probe containing the entire *S. cerevisiae* coding sequence of TBP (*SPT15*) was hybridized to genomic DNA preparations from *S. cerevisiae* and *Candida albicans* that were digested with various restriction enzymes. At low stringency (0.2X SSC, room temperature hybridization) the
20 probe efficiently hybridized as expected to known restriction bands in the *S. cerevisiae* digests, but did not detectably hybridize to any restriction band of the *Candida albicans* digests. The *Saccharomyces* sequences were detectable on an autoradiograph with less than 10 minutes of exposure. By contrast, even with one week of exposure, there was no detectable hybridization of the same probe to the *Candida albicans* DNA. The conclusion
25 from these observations is that it is likely that the DNA sequence of the *Candida albicans* gene had diverged quite significantly from the *S. cerevisiae* sequence, and thus Southern hybridization, PCR strategies or other cloning methods based on hybridization of complementary nucleic acid sequences are unlikely to lead to cloning of the *Candida albicans* homolog of SPT15.
30 The approach used to clone the *Candida albicans* homolog of TFIIB involved genetic complementation of mutant *S. cerevisiae* strains. A library of *Candida albicans* genomic sequences was introduced into a strain of *S. cerevisiae* that contained

a mutated TFIIB gene (SUA7). This mutant strain was capable of growth at 30° C, but was non-viable at 37° C, due to a temperature sensitive mutation in the TFIIB gene. Following transformation of the library into the strain, the cells were grown at 37° C, and the colonies which grew at this non-permissive temperature were further studied as 5 potentially carrying a *Candida albicans* homolog of the defective gene. Plasmids were purified from the various isolates which were viable at 37° C. After candidate clones were isolated by growth at the nonpermissive temperature, the library plasmid was recovered from the cell and retested to confirm that the *C. albicans* sequences on the plasmid were substituting for the *S. cerevisiae* gene. Subclones of *C. albicans* sequences were 10 constructed by standard cloning methods, and the minimal *Candida* DNA sequence that substituted was sequenced using standard methods. Digestion of these plasmids revealed a common DNA fragment approximately 1.35 kb in length, which when subcloned into pRS316 proved to complement multiple independent SUA7 strains of *S. cerevisiae*. This DNA fragment was sequenced, and confirmed *C. albicans* SUA7 sequence homology to 15 *S. cerevisiae* SUA7.

The nucleotide sequence encoding *Candida albicans* TBP and the predicted amino acid sequence of the encoded protein are presented in Fig. 1 (SEQ ID NOS: 1 and 2). The nucleotide sequence encoding *Candida albicans* TFIIB and the predicted amino acid sequence of the encoded protein are presented in Fig. 2 (SEQ ID NOS: 3 and 4). 20

Methods For Screening Potential Inhibitors of *Candida albicans* Growth and/or Viability
Because TFIIB is essential for transcription initiation, the recombinant *Candida albicans* TFIIB gene and recombinant protein encoded by this gene may be utilized in screening assays for inhibitors of *Candida albicans* growth and viability. The 25 screening assays of this invention detect inhibition of the *Candida albicans* TFIIB-mediated transcription initiation, either by measuring inhibition of transcription, transcription initiation, or initiation complex formation, or by assaying formation of a protein/DNA or a protein/protein complex.

EXAMPLE 1Screening for Inhibitors of Transcription

a) Transcription Assay Components.

An *in vitro* transcription assay consisting of the minimal components necessary to synthesize an mRNA transcript from a DNA template can be used to screen for inhibition of mRNA production. The elements of such an assay consist of; a) a DNA template, b) RNA polymerase II, c) recombinant *Candida albicans* TFIIB, and d) a TBP which is preferably *Candida albicans* TBP. In order to increase the efficiency of transcription, additional components of the transcription complex may be included, as desired; e.g., TFIIE, TFIIF, TFIIH, etc.

Parvin and Sharp (*Cell* 73, 533-540, 1993) have reconstituted gene transcription *in vitro* with a minimal reaction containing a DNA template, RNA polymerase II, TFIIB, and TBP. For efficient transcription under minimal conditions, the DNA template (a) is supercoiled, and (b) possesses a promoter region containing a TATA consensus region. Additionally, Lue et al. (*Science* 246, 661-664, 1989) have determined that transcription may be detected most efficiently with a DNA template devoid of guanosine residues (a G-minus or G-less cassette). Promoter dependence is demonstrated by the loss of signal when a plasmid lacking promoter sequences is utilized as a template. Correct initiation is demonstrated by the production of a band with a mobility consistent with the size of the expected product on denaturing polyacrylamide electrophoresis gels.

As stated above, *Candida albicans* TFIIB forms a transcription initiation complex with RNA polymerase II. Therefore, it is desired that an *in vitro* transcription assay according to the invention contain RNA polymerase II. Although it is possible to perform an inhibitor screening assay using RNA polymerase II from a yeast strain other than *Candida albicans*, e.g., *S. cerevisiae*, it is most desirable to use a homologous assay in which the transcription complex components are from *Candida albicans*.

A method for *S. cerevisiae* RNA polII purification is described in Edwards et al. (*Proc. Natl. Acad. Sci. USA* 87: 2122-2126 (1990)). Alternatively, highly purified RNA polymerase II from *Candida albicans* was provided as follows.

RNA polymerase II activity was measured in reactions containing 50 mM Tris-Cl, pH 7.9 (4° C), 50 mM (NH₄)₂ SO₄, 2.5 mM MnCl₂, 0.1 mM EDTA, 5 mM DTT, 100 µg/ml BSA, 0.6 mM ATP, CTP and GTP, 25 µM UTP (2.5 µCi) [α -³²P] UTP and 100 µg/ml heat-denatured calf thymus DNA in a final volume of 50 µl. Reactions

were incubated for 60 min. at 30° C and terminated by addition of 50 µl 15% (w/v) trichloroacetic acid. Acid-insoluble radioactivity was collected by filtration through glass fiber filters and quantified by liquid scintillation spectrophotometry. One unit of RNA polymerase activity catalyzes the incorporation of 1 pmol of UTP into acid-insoluble material in 60 min. under the conditions described above.

5 *Candida albicans* was obtained from the American Type Culture Collection (ATCC 10231) and cultured in YPD medium (Current Protocols in Molecular Biology, Vol. 2, 13, Suppl. 19 (1989)) at 30° C with vigorous agitation and aeration. All procedures were carried out at 4° C using 18 liter cultures. Cells were harvested by
10 centrifugation (5000 rpm, 10 min., Sorvall H6000 rotor), washed once with ~ 11 ice-cold deionized water and repelleted as above. The cell pellet (200-300 g wet weight) was thoroughly resuspended in a volume of Buffer A (50 mM Tris-HCl, pH 7.9, 4° C, 10% glycerol, 1 mM EDTA, 5 mM MgCl₂, and protease inhibitor) containing 300 mM (NH₄)₂ SO₄ equivalent to the packed volume of cells (determined by weight assuming a density
15 of 1 g/ml cells). Resuspended cells were either processed immediately as described below or frozen by pipetting into liquid N₂ and stored at -80 C. Frozen cells were thawed on ice prior to proceeding. Following the addition of NP-40 to a final concentration of 0.1%, cells were disrupted by grinding with 1 ml acid-washed glass beads/ml cell suspension (Sigma, 400-625 µM) using 12 bursts of 30 sec. each in a Bead Beater
20 (BioSpec). Glass beads were allowed to settle out and the supernatant was centrifuged at 30,000 x g for 40 min. Solid (NH₄)₂ SO₄ was slowly added to a final concentration of 0.4 g/ml supernatant and the resulting precipitate was pelleted by centrifugation at 100,000 x g for 30 min. The pellet was resuspended with a volume of Buffer A sufficient to yield a conductivity equivalent to Buffer A containing 75 mM (NH₄)₂ SO₄.

25 Following centrifugation of the resuspension at 10,000 x g for 10 min, this supernatant (~ 1- 1.5 mg protein/ml) was loaded onto a 300 ml DE-52 DEAE-cellulose column equilibrated with Buffer A containing 75 mM(NH₄)₂ SO₄. After washing with 5 column volumes Buffer A containing 75 mM (NH₄)₂ SO₄, and 5 column volumes Buffer A containing 0.15 M (NH₄)₂ SO₄, RNA polymerase II was eluted with 5 column volumes
30 Buffer A containing 0.4 M (NH₄)₂ SO₄. Fractions were collected containing the peak of protein, determined by absorbance at 280 nm and pooled. The pool was dialyzed against Buffer A containing 20% glycerol for 3 hr. at 4° C.

The 0.4 M (NH₄)₂ SO₄ eluate from DEAE-cellulose (261 mg protein, 290 ml) was diluted with sufficient Buffer A to lower the conductivity to the equivalent of Buffer A containing 0.15 M (NH₄)₂ SO₄, centrifuged at 10,000 x g for 10 min. and the supernatant was loaded at a flow rate of 30 ml/hr onto an 30 ml DEAE-cellulose column
5 equilibrated with Buffer A containing 0.15 M (NH₄)₂ SO₄. After washing with 3 column volumes of Buffer A containing 0.15 M (NH₄)₂ SO₄, the column was developed with a 200 ml linear gradient of 0.15 - 0.4 M(NH₄)₂ SO₄ in Buffer A at a flow rate of 45 ml/hr. Fractions from the single peak of amanitin-sensitive RNA polymerase activity, eluting around 0.22 M (NH₄)₂ SO₄, were pooled (21.1 mg protein, 45 ml) and loaded directly
10 onto a 5 ml Heparin agarose column equilibrated with Buffer A containing 0.2 M (NH₄)₂ SO₄. The column was washed with 3 column volumes of Buffer A containing 0.2 M (NH₄)₂ SO₄ and developed with an 80 ml linear gradient of 0.2 - 0.6 M (NH₄)₂ SO₄ in Buffer A. The active fractions, which eluted at approximately 0.42 M (NH₄)₂ SO₄ were
15 pooled (2.0 mg protein, 15 ml), frozen in 300 µl aliquots in liquid N₂, and stored at -80° C where activity was stable for at least 6 months.

Purification of protein initiation factors used in the assay is accomplished by standard methods known in the art (e.g., phosphocellulose chromatography followed by gel filtration), as described in (*Nature* 346, 387-390 (1990)).

To screen for Candida albicans TFIIB-mediated transcription inhibition, a
20 transcription assay is reconstituted using recombinant Candida albicans TFIIB. Candida albicans TFIIB is expressed in and purified from *E. coli* as described in Buratowski, 1993, *Proc. Natl. Acad. Sci.* 90:5633. Supercoiled plasmid DNA containing the CYC1 promoter linked to the G-less cassette described by Lue *et al.* (*Science* 246, 661-664 (1989)), is purified by standard methods for purification of supercoiled circular DNA
25 (Current Protocols in Molecular Biology, Vol. 2, 13, Suppl. 19 (1989)). 10 - 100 ng of Candida albicans TFIIB, 10 - 100 ng of Candida albicans TBP, 10 - 100 ng Candida albicans RNA polymerase II and 1 µg plasmid DNA are added to 50 µl reaction mixtures containing 50 mM HEPES, pH 7.5, 10% glycerol, 90 mM potassium glutamate, 0.75% polyethylene glycol (molecular weight 3350), 10 mM magnesium acetate, 5 mM EGTA,
30 5 mM DTT, 0.4 mM ATP, 0.4 mM CTP, 10 µM [α -³²P]UTP, 0.2 mM 3'-O-methyl-GTP, and containing or lacking a candidate inhibitor molecule. Reactions are incubated at 30° C for 30 - 60 min. and RNA synthesis is detected as described below.

b) Detection of Transcribed RNA.

The detection of newly transcribed RNA is achieved by standard methods (Current Protocols in Molecular Biology, Vol. 1, 4.10, Suppl 24 (1989)). As one example, RNA synthesis can be detected as incorporation of a radioactively or 5 fluorescently labeled nucleotide into higher molecular weight RNA products, determined by one of the following methods: 1) acid-insoluble labeled material quantitated by the appropriate method (e.g. scintillation counting for radioactive precursors, fluorometry for fluorescent precursors); 2) labeled reaction product that hybridizes to oligonucleotides complementary to the correctly initiated transcript (i.e., northern blot analysis); 3) the 10 presence of a labeled band with the appropriate mobility detected by autoradiography, on denaturing polyacrylamide electrophoresis gels; 4) any other method that discriminates mononucleotides from polynucleotides, where polynucleotides are the desired RNA product. Such methods may utilize one or more well known techniques of molecular biology (Current Protocols in Molecular Biology, Vol. 2, 13, Suppl. 19 (1989)), for 15 example; UV analysis; affinity systems (e.g., affinity chromatography, nitrocellulose filtration, biotin/streptavidin systems, immunoaffinity,) (Current Protocols in Molecular Biology, Vol. 2, 13, Suppl. 19 (1989)); and high performance liquid chromatography.

The inclusion of an inhibitor molecule that interferes with *Candida albicans* TFIIB biological activity inhibits transcription. In this assay inhibition is measured as a 20 reduction in the amount of mRNA transcript produced relative to the amount of mRNA transcript produced in the absence of the inhibitor (the positive control). A decrease in amount of mRNA transcript is indicative of an inhibitor. The determination of effective levels of mRNA transcript inhibition is described below.

25 **EXAMPLE 2**

Screening for Inhibition of DNA-Protein Complex Formation

A DNA-protein binding assay consisting of the minimal components necessary to permit DNA-*Candida albicans* TFIIB association to occur can be used to screen for inhibition of the formation of the DNA-TBP-*Candida albicans* TFIIB complex 30 during transcription initiation. The components of such an assay include: a) a DNA template, b) recombinant *Candida albicans* TFIIB, c) TBP, preferably from C. albicans, and optionally d) a candidate *Candida albicans* TFIIB inhibitor.

The inclusion of an inhibitor molecule that interferes with the interaction between the *Candida albicans* TFIIB and the DNA template inhibits transcription initiation. The inhibitor may interact directly with the *Candida albicans* TFIIB protein, and/or it may interact with TBP and/or with the DNA template at the site of TFIIB/TBP binding. In this assay inhibition is measured as a reduction in the amount of DNA-TBP-TFIIB complex produced relative to the amount of DNA-TBP-TFIIB complex produced in the absence of the inhibitor (the positive control). A decrease in the amount of DNA-TBP-TFIIB complex is indicative of an inhibitor. Determination of effective levels of DNA-TBP-TFIIB inhibition is described below.

One DNA binding assay is constructed as follows. 10 - 100 ng *Candida albicans* TFIIB, expressed in and purified from *E. Coli* as described above, is incubated with 0.5 ng labeled (e.g. radioactively or fluorescently labeled) oligonucleotide containing a TATA element such as the one described by Buratowski *et al.* (*Cell* 56, 549-561 (1989)) and 10 - 100 ng *Candida albicans* TBP in reactions containing 10 - 20 mM HEPES (or equivalent), pH 7.5 - 8.0, 5 mM MgCl₂, 12% glycerol, 10 mM dithiothreitol (DTT), 100 µg/ml BSA, 5 - 20 µg/ml poly (dG-dC):(dG-dC) and a candidate inhibitor of complex formation. Reactions are incubated at 30° C for 30-60 min.

Formation of a DNA-TBP-TFIIB complex may be detected as retention of labeled DNA (the label being detected by an appropriate methodology such as scintillation counting for radiolabeled DNA or fluorometry for fluorescently labeled DNA) utilizing known affinity methods for protein immobilization (e.g., biotin/streptavidin, nitrocellulose filtration, affinity chromatography, immunoaffinity). Nonretention of labeled DNA due to the failure of *Candida albicans* TFIIB-TBP-DNA complex formation is indicative of an effective inhibitor.

Complex formation may also be detected as retention of labeled *Candida albicans* TFIIB (e.g. radioactively, fluorescently) utilizing known methods for immobilizing DNA. Nonretention of labeled *Candida albicans* TFIIB due to the failure of *Candida albicans* TFIIB-TBP-DNA complex formation is indicative of an effective inhibitor. The preceding two methods are suitable for high-throughput chemical compound library screening applications such as those commonly used in drug discovery.

A third example of detecting DNA/protein complex formation involves detection of an electrophoretic mobility shift of labeled DNA on 4% polyacrylamide gels containing 5% (v/v) glycerol, 25 mM Tris, 100 mM glycine, 1mM EDTA, 5 mM MgCl₂,

pH 8.3 in the presence of *Candida albicans* TFIIB and TBP. The position of the labeled oligonucleotide is detected by appropriate methods (e.g., autoradiography for radioactive oligonucleotide). The absence or deviation of the expected mobility shift due to DNA-*Candida albicans* TFIIB complex formation is indicative of an effective inhibitor.

5 Finally, other methods for detecting or separating DNA-protein complexes may be used, including UV crosslinking analysis, high performance liquid chromatography, phage display technology (U.S. Patent No. 5,403,484. Viruses Expressing Chimeric Binding Proteins), and surface plasmon resonance (Biacore, Pharmacia Biosensor, North America) as described below.

10

EXAMPLE 3

Screening for Inhibition of Protein-Protein Complex Formation

A protein-protein binding assay consisting of the minimal components necessary to permit *Candida albicans* TBP-*Candida albicans* TFIIB binding to occur can be used to screen for inhibition of the formation of the *Candida albicans* TBP-*Candida albicans* TFIIB complex during transcription initiation. The elements of such an assay consist of; a) recombinant *Candida albicans* TFIIB, b) TBP, preferably a recombinant *Candida albicans* TBP, and optionally c) a candidate inhibitor of binding.

5 The inclusion of an inhibitor molecule that interferes with the interaction between the *Candida albicans* TBP and *Candida albicans* TFIIB inhibits transcription initiation. The inhibitor may interact with the *Candida albicans* TBP or TFIIB protein and thus induce a conformational change which prevents binding, or it may directly inhibit the interaction of *Candida albicans* TFIIB and TBP proteins. In this assay, inhibition is measured as a reduction in the amount of *Candida albicans* TBP-TFIIB complex produced relative to the amount of *Candida albicans* TBP-TFIIB complex produced in the absence of the inhibitor (the positive control). A decrease in the amount of TFIIB-TBP complex 10 is indicative of an inhibitor. Determination of effective levels of inhibition of *Candida albicans* TBP-TFIIB binding is described below.

15 One assay for formation of *Candida albicans* TBP-TFIIB complex is provided as follows. 10 - 100 ng *Candida albicans* TFIIB and 10 - 100 ng *Candida albicans* TBP are expressed in and purified from *E. coli* as described above, and are added to reactions containing 10 - 20 mM HEPES (or equivalent), pH 7.5 - 8.0, 5 mM

MgCl₂, 12% glycerol, 10 mM dithiothreitol (DTT) 100 µg/ml BSA, and a candidate inhibitor. The mixture is then incubated at 30° C for 30 - 60 min.

Formation of a complex comprising *Candida albicans* TBP and *Candida albicans* TFIIB may be detected by an electrophoretic mobility shift of labeled (e.g. radioactive or fluorescent) TBP or TFIIB on 4% polyacrylamide gels containing 5% (v/v) glycerol, 25 mM Tris, 100 mM glycine, 1mM EDTA, 5 mM MgCl₂, pH 8.3 in the presence of the unlabeled partner. The position of the labeled partner is detected by appropriate methods (e.g., autoradiography for radioactive oligonucleotide). The absence or deviation of the expected mobility shift due to *Candida albicans* TFIIB-TBP complex formation is indicative of an effective inhibitor.

Formation of a complex comprising *Candida albicans* TBP and *Candida albicans* TFIIB may be detected as retention of labeled TBP utilizing known affinity methods for immobilizing the *Candida albicans* TFIIB protein (e.g., biotin/streptavidin, nitrocellulose filtration, affinity chromatography, immunoaffinity). The failure of formation of the *Candida albicans* TFIIB-TBP complex is indicative of inhibition, and is indicated by nonretention of labeled TBP. Alternatively, the immobilized element may be *Candida albicans* TBP and the labeled partner *Candida albicans* TFIIB.

In the above example, a stronger signal may be conferred in the presence of both TBP and TFIIB and, in addition, a DNA template containing a TATA element. The complex is then quantitated by autoradiography, Phosphorimager technology, or scintillation counting for radioactively labeled factors, fluorometry for fluorescently labeled factors, luminometry for factors labeled with ligands that are detected using chemiluminescent or phosphorescent probing methodologies, or other similar detection methods or materials labeled as described above that are standard in the art.

Other methods for detecting or separating protein-protein complexes may be used, including UV crosslinking analysis, high performance liquid chromatography, phage display technology, and surface plasmon resonance as described herein.

EXAMPLE 4

Assay for Formation of TBP-TFIIB-RNA Polymerase II-DNA Complex

Formation of a TBP, TFIIB, RNA polymerase II, DNA complex is known to be markedly stimulated by the addition of another factor, TFIIF. Previous data indicates that TFIIF from *S. cerevisiae* can function in species as distantly related as

5

Schizosaccharomyces pombe and humans, strongly suggesting that this factor can functionally replace its *C. albicans* homolog. Accordingly, this factor is purified from *S. cerevisiae* by published methods (Sayre, 1992, J. Biol. Chem. 267:23383) and used to reconstitute formation of a complex containing *C. albicans* TBP, TFIIB, RNA polymerase II and promoter containing DNA such as that described for reconstitution of the TFIIB-TBP-DNA complex.

10

15

20

25

30

Complex formation is carried out in reactions containing, for example, 10 - 100 ng *Candida albicans* TBP, 10 - 100 ng *Candida albicans* TFIIB, 10 - 100 ng *Candida albicans* RNA polymerase II, 10 - 100 ng *S. cerevisiae* TFIIF, 0.5 ng double-stranded TATA element containing-oligonucleotide (same as that used for TFIIB-TBP-DNA complex assay), 10 - 20 mM HEPES (or equivalent), pH 7.5 - 8.0, 5 mM MgCl₂, 12% glycerol, 10 mM dithiothreitol (DTT), 100 µg/ml BSA, 5 - 20 µg/ml poly (dG-dC); (dG-dC) and compound(s) to be tested for inhibitory activity. Following incubation at 30° C for 30 - 60 min, complexes are detected by one of the methods described above for the TBP-TFIIB-DNA complex. The TBP-TFIIB-RNA polymerase II-DNA complex has a slower electrophoretic mobility than the TBP-TFIIB-DNA complex identified by using the electrophoretic method. In addition, complex formation can be detected as TBP, TFIIB-dependent retention of RNA polymerase II activity (measured by incorporation of labeled nucleotide precursors into acid-insoluble product using the assay for RNA polymerase activity described in the RNA polymerase II purification protocol above) on a matrix with bound TATA-element containing DNA. The IC₅₀ of inhibitory compounds will be determined by titration into reactions reconstituted as described above. The IC₅₀ of these compounds against reactions reconstituted with human TBP, TFIIB and RNA polymerase II will also be determined by the same method. Human RNA polymerase II and TFIIF are purified as described previously (Flores et al., 1990, J. Biol. Chem. 265:5629-5634; Reinberg et al., J. Biol. Chem 262:3310-3321). Those compounds whose IC₅₀ against reactions containing *C. albicans* factors is ≤ 1/5 of their IC₅₀ against reactions reconstituted with human factors will be tested for their ability to inhibit *C. albicans* growth as described below.

EXAMPLE 5Phage Display Inhibitor Screening

In addition to the above mentioned standard techniques of the art, other technologies for molecular identification can be employed in the identification of inhibitor molecules. One of these technologies is phage display technology (U.S. Patent No. 5,403,484. Viruses Expressing Chimeric Binding Proteins). Phage display permits identification of a binding protein against a chosen target. Phage display is a protocol of molecular screening which utilizes recombinant bacteriophage. The technology involves transforming bacteriophage with a gene that encodes an appropriate ligand (in this case, a candidate inhibitor) capable of binding to the target molecule of interest. For the purposes of this disclosure, the target molecule may be *Candida albicans* TFIIB, or a DNA-protein or protein-protein complex formed using TBP and/or TFIIB, as described herein. The transformed bacteriophage (which preferably is tethered to a solid support) express the candidate inhibitor and display it on their phage coat. The cells or viruses bearing the candidate inhibitor which recognize the target molecule are isolated and amplified. The successful inhibitors are then characterized.

Phage display technology has advantages over standard affinity ligand screening technologies. The phage surface displays the microprotein ligand in a three dimensional conformation, more closely resembling its naturally occurring conformation. This allows for more specific and higher affinity binding for screening purposes.

EXAMPLE 6Biospecific Interaction Analysis

A second relatively new screening technology which may be applied to the inhibitor screening assays of this invention is biospecific interaction analysis (BIAcore, Pharmacia Biosensor AB, Uppsala, Sweden). This technology is described in detail by Jonsson et al. (Biotechniques 11:5, 620-627 (1991)). Biospecific interaction analysis utilizes surface plasmon resonance (SPR) to monitor the adsorption of biomolecular complexes on a sensor chip. SPR measures the changes in refractive index of a polarized light directed at the surface of the sensor chip.

Specific ligands (i.e., candidate inhibitors) capable of binding to the target molecule of interest (i.e., *Candida albicans* TFIIB or a protein-protein or protein-DNA complex containing TFIIB) are immobilized to the sensor chip. In the presence of the

target molecule, specific binding to the immobilized ligand occurs. The nascent immobilized ligand-target molecule complex causes a change in the refractive index of the polarized light and is detected on a diode array. Biospecific interaction analysis provides the advantages of; 1) allowing for label-free studies of molecular complex formation; 2) studying molecular interactions in real time as the assay is passed over the sensor chip; 5 3) detecting surface concentrations down to 10 pg/mm²; detecting interactions between two or more molecules; and 4) being fully automated (Biotechniques 11:5, 620-627 (1991)).

EXAMPLE 7

High Throughput Screening of Potential Inhibitors

It is contemplated according to the invention that the screening methods disclosed herein encompass screening of multiple samples simultaneously, also referred to herein as 'high throughput' screening. For example, in high throughput screening, from several hundred to several thousand candidate inhibitors may be screened in a single 15 assay. An example of high throughput screening assay useful according to the invention is as follows.

A protein A (pA)- *Candida albicans* TFIIB fusion protein is generated by inserting the coding sequence of TFIIB in frame downstream of the pA coding sequence of the plasmidRIT2T (Pharmacia Biotech). The fusion construct is induced, and the 20 resultant recombinant protein is extracted and purified according to the manufacturer's recommended conditions. This procedure can also be carried out for the preparation of a pA- *Candida albicans* TBP fusion protein except that the downstream coding sequence is that of TBP protein; all other steps would remain the same.

A Dynatech Microlite 2 microliter plate, or equivalent high protein-binding capacity plate, is coated with 1 µg/well human IgG by incubating 300 µl 3.33 µg/ml human IgG (Sigma) in coating buffer (0.2 M sodium carbonate, pH 9.4) in the well for 4-12 hr at 4°C. The coating buffer is then decanted and the wells are washed five times with 300 µl PBS. 300 µl blocking buffer (SuperBlock™ blocking buffer; Pierce) containing 3.33 µg/ml pA- TFIIB or pA-TFIIB are added and the plate is incubated for 30 4 or more hours at 4°C. The plates may be stored in this form at 4°C until ready for use. When ready for use the plates are washed five times with 300 µl PBS. Test compound at a final concentration of 20-200 µM and labeled TFIIB or TBP (i.e., nonfusion protein), whichever is not added during the coating step, and 10 - 1000 fmol DNA

containing a TATA sequence, are suspended in HEG buffer containing 200 µg/ml BSA in a total volume of 150 µl and are added and the reaction is incubated at room temperature with gentle agitation for 60 min. The plate is then washed five times with PBS using a Dynatech plate washer or equivalent. Bound labeled protein is quantitated by adding 250 µl Microscint (Packard) per well and is counted in a microtiter plate-compatible scintillation spectrophotometer.

As an alternative, the protein A fusion and the second, non-fusion protein can be incubated in the presence of test compound in polypropylene microtiter plates under the same buffer and incubation conditions described above. The reaction mix is then transferred to the wells of a microtiter plate coated with human IgG (which is prepared as described above, and is stored in blocking buffer and is washed five times with 300 µl PBS immediately before use) and is incubated for 60 min at room temperature with gentle agitation. Retention of radioactive protein is quantified as above.

Interaction of TBP and TFIIB, which is measured as retention of radioactivity on the plate, is dependent on human IgG coating the plate and wild-type Candida albicans TBP or TFIIB, one of which must be fused to pA. Candidate inhibitors or extracts that inhibit retention of radioactivity by more than 30% are identified and the inhibitory activity is further purified if necessary. Inhibitors identified as described above are then tested for their ability to inhibit Candida albicans TFIIB-dependent transcription in an *in vitro* transcription system such as that described herein, and also may be tested for their ability to inhibit Candida albicans growth.

Other fusion or modified protein systems that are contemplated include, but are not limited to, glutathione-S-transferase, maltose binding protein, influenza virus hemagglutinin, FLAG™ and hexahistidine fusions to Candida albicans TBP or Candida albicans TFIIB which are prepared, expressed, and purified by published methods or biotinylated Candida albicans TBP or TFIIB which are prepared using reactive biotin precursors available commercially. The purified fusion or modified protein is immobilized on a microtiter plate containing the appropriate ligand for each fusion protein (e.g. glutathione, amylose, CA157 antibody, etc., respectively) and the assay is carried out and the results evaluated in essentially the same manner as described above.

EXAMPLE 8Candidate Inhibitors

A "candidate inhibitor," as used herein, is any compound with a potential to inhibit *Candida albicans* TFIIB-mediated transcription initiation or complex formation.

5 A candidate inhibitor is tested in a concentration range that depends upon the molecular weight of the molecule and the type of assay. For example, for inhibition of protein/protein or protein/DNA complex formation or transcription initiation, small molecules (as defined below) may be tested in a concentration range of 1pg - 100 ug/ml, preferably at about 100 pg - 20 ug/ml; large molecules, e.g., peptides, may be tested in 10 the range of 10 ng - 100 ug/ml, preferably 100 ng - 10 ug/ml.

Inhibitors of *Candida albicans* growth or viability may target the novel transcription factor described herein, TFIIB, or it may target a protein or nucleic acid that interacts with the novel transcription factor so as to prevent the natural biological interaction that occurs *in vivo* and leads to transcription initiation in Candida. Thus, an 15 inhibitor identified as described herein will possess two properties: 1) at some concentration it will inhibit *Candida albicans* growth or viability; and 2) at the same concentration, it will not significantly affect the growth of mammalian, particularly human, cells.

Candidate inhibitors will include peptide and polypeptide inhibitors having 20 an amino acid sequence based upon the novel TFIIB sequences described herein. For example, a fragment of TFIIB may act as a competitive inhibitor with respect to TFIIB binding to other proteins involved in Candida transcription, e.g., RNA polymerase II, TBP, or with respect to binding of the transcription complex to the DNA template. One such candidate fragment is a fragment of TFIIB containing a classic zinc finger motif 25 (sequence). This fragment spans a 35 amino acid region defined by residues 22-46 of the TFIIB sequence.

Candidate inhibitor compounds from large libraries of synthetic or natural 30 compounds can be screened. Numerous means are currently used for random and directed synthesis of saccharide, peptide, and nucleic acid based compounds. Synthetic compound libraries are commercially available from a number of companies including Maybridge Chemical Co. (Trevillet, Cornwall, UK), Comgenex (Princeton, NJ), Brandon Associates (Merrimack, NH), and Microsource (New Milford, CT). A rare chemical library is available from Aldrich (Milwaukee, WI). Combinatorial libraries are available and can

be prepared. Alternatively, libraries of natural compounds in the form of bacterial, fungal, plant and animal extracts are available from e.g. Pan Laboratories (Bothell, WA) or MycoSearch (NC), or are readily producable. Additionally, natural and synthetically produced libraries and compounds are readily modified through conventional chemical, physical, and biochemical means.

Useful compounds may be found within numerous chemical classes, though typically they are organic compounds, and preferably small organic compounds. Small organic compounds have a molecular weight of more than 50 yet less than about 2,500 daltons, preferably less than about 750, more preferably less than about 350 daltons. Exemplary classes include heterocycles, peptides, saccharides, steroids, and the like. The compounds may be modified to enhance efficacy, stability, pharmaceutical compatibility, and the like. Structural identification of an agent may be used to identify, generate, or screen additional agents. For example, where peptide agents are identified, they may be modified in a variety of ways to enhance their stability, such as using an unnatural amino acid, such as a D-amino acid, particularly D-alanine, by functionalizing the amino or carboxylic terminus, e.g. for the amino group, acylation or alkylation, and for the carboxyl group, esterification or amidification, or the like. Other methods of stabilization may include encapsulation, for example, in liposomes, etc.

EXAMPLE 9

Measurement for effective inhibition

The amount of inhibition by a candidate inhibitor is quantified using the following formula, which describes reactions reconstituted with a radioactively labeled moiety:

$$\text{Percent Inhibition} = \frac{(CPM_{\text{Positive Control}} - CPM_{\text{Sample}})}{(CPM_{\text{Positive Control}})} \times 100$$

where $CPM_{\text{Positive Control}}$ is the average of the cpm in complexes or RNA molecules formed in reactions that lack the candidate inhibitor, and CPM_{Sample} is the cpm in complexes formed in reactions containing the candidate inhibitor. Candidate inhibitors for which the percent inhibition is 50% are titrated into reactions containing either Candida albicans

TFIIB or human TFIIB (expressed in and purified from *E. coli* using existing recombinant clones (Peterson et al., *Science* 248, 1625-1630, 1990; Kao et al., *Science* 248, 1646-1650, 1990; Hoffman, et al., *Nature* 346, 387-390, 1990, and assayed as described above) and their IC₅₀ with respect to human and *Candida albicans* TFIIB determined from graphs of compound concentration vs. % inhibition. The IC₅₀ is defined as the concentration that results in 50% inhibition. Candidate inhibitors for which the IC₅₀ against *Candida albicans* TFIIB-containing reactions is less than or equal to 1/5 the IC₅₀ against human TFIIB-containing reactions are further tested for their ability to inhibit the growth of *Candida albicans* in culture as described below.

10

EXAMPLE 10

Measurement for inhibition of *Candida albicans* growth in culture

Once an inhibitor is identified in one or more of the binding or transcription assays described herein, it may be desirable to determine the effect of the inhibitor on the growth and/or viability of *Candida albicans* in culture. A candidate inhibitor is tested for its ability to inhibit growth of *Candida albicans* cells in culture as follows. Methods for performing tests on growth inhibition in culture are well-known in the art. Once such procedure is based on the NCCLS M27P method (The National Committee for Clinical Laboratory Standards, Reference Method for Broth Dilution Antifungal Susceptibility Testing of Yeasts; proposed standard, 1992), as follows. Serial dilutions (two- or three-fold steps starting from a maximum concentration of 100 - 200 µg/ml) of candidate inhibitor are prepared using RPMI-1640 medium as diluent and an aliquot of 100 µl of each dilution is added to the wells of a 96-well polystyrene microtiter plate. Five *Candida albicans* colonies, picked from a Sabouraud Dextrose Agar plate inoculated 14-20 hr previously with the test *Candida albicans* strain (Catalog number 10231 from the American Type Culture Collection Yeast Catalog), are suspended with RAMI-1640 medium such that the density of cells is 10,000 - 30,000 cells/ml. 100µl of the cell suspension is added to each of the wells of the 96-well microtiter plate containing diluted candidate inhibitor and medium control. Cultures are mixed by agitation and incubated at 35°C for 48 hr without agitation, after which cell growth is monitored by visual inspection for the formation of turbidity and/or mycelial colonies. The minimum concentration of candidate inhibitor at which no cell growth is detected by this method is defined as the minimum inhibitory concentration (MIC) for that compound. Examples of MICs for

known antifungal compounds obtained using this technique are 0.125 - 0.5 $\mu\text{g}/\text{ml}$ for fluconazole and 0.25 - 1.0 $\mu\text{g}/\text{ml}$ for amphotericin B (The National Committee for Clinical Laboratory Standards, Reference Method for Broth Dilution Antifungal Susceptibility Testing of Yeasts; proposed standard, 1992). An inhibitor identified by the methods described herein, will have MIC which is equivalent to or less than the MICs for fluconazole or amphotericin B.

EXAMPLE 11

Transcription Inhibition Counterscreen Using Human TFIIB

A compound identified as an inhibitor of *Candida albicans* according to one or more of the assays described herein may be tested further in order to determine its effect on the host organism. In the development of useful antifungal compounds for human therapeutics, it is desirable that such compounds act as effective agents in inhibiting the viability of the fungal pathogen while not significantly inhibiting human cell systems. Specifically, inhibitors of *Candida albicans* identified in any one of the above described assays may be counterscreened for inhibition of human TFIIB.

Recombinant human TFIIB can be obtained from existing sources and purified by published methods (for example, see Peterson et al., Kao et al., and Hoffman et al., supra) and contacted with the candidate inhibitor in assays such as those described above using a human system. The effectiveness of a *Candida albicans* TFIIB inhibitor as a human therapeutic is determined as one which exhibits a low level of inhibition against human TFIIB relative to the level of inhibition with respect to *Candida albicans* TFIIB. For example, it is preferred that the amount of inhibition by a given inhibitor of human TFIIB in a human system be no more than 20% with respect to the amount of inhibition of *Candida albicans* TFIIB in a *Candida* system when tested in any of the assays described above.

Dosage and Pharmaceutical Formulations

For therapeutic uses, inhibitors identified as described herein may be administered in a pharmaceutically acceptable/biologically compatible formulation, for example, in the form of a cream, ointment, lotion or spray for topical use, or in a physiological solution, such as a salt solution, for internal administration. The amount of inhibitor administered will be determined according to the degree of pathogenic

5

infection and whether the infection is systemic or localized, and will typically be in the range of about 1ug - 100 mg/kg body weight. Where the inhibitor is a peptide or polypeptide, it will be administered in the range of about 100 - 500 ug/ml per dose. A single dose of inhibitor or multiple doses, daily, weekly, or intermittently, is contemplated according to the invention.

The route of administration will be chosen by the physician, and may be topical, oral, transdermal, nasal, rectal, intravenous, intramuscular, or subcutaneous.

Budapest Treaty Deposit

10

E. coli transformed with a plasmid containing the gene encoding *Candida albicans* TBP has been deposited in an international depository, the A.T.C.C., Rockville, MD, under the accession number 69900, on September 15, 1995. *E. coli* transformed with a plasmid containing the gene encoding *Candida albicans* TFIIB has been deposited in an international depository, the A.T.C.C., Rockville, MD, under the accession number 69899, on September 15, 1995. A.T.C.C. Nos. 69900 and 69889 will be available to the public upon the grant of a patent which discloses the accession numbers in conjunction with the invention described herein. The deposits were made under the Budapest Treaty, will be available beyond the enforceable life of the patent for which the deposit is made, and will be maintained for a period of at least 30 years from the time of deposit and at least 5 years after the most recent request for the furnishing of a sample of the deposit is received by the A.T.C.C. It is to be understood that the availability of these deposits does not constitute a license to practice the subject invention in derogation of patent rights granted for the subject invention by governmental action.

25

OTHER EMBODIMENTS

The foregoing examples demonstrate experiments performed and contemplated by the present inventors in making and carrying out the invention. It is believed that these examples include a disclosure of techniques which serve to both apprise the art of the practice of the invention and to demonstrate its usefulness. It will be appreciated by those of skill in the art that the techniques and embodiments disclosed herein are preferred embodiments only that in general numerous equivalent methods and techniques may be employed to achieve the same result.

All of the references identified hereinabove, are hereby expressly incorporated herein by reference to the extent that they describe, set forth, provide a basis for or enable compositions and/or methods which may be important to the practice of one or more embodiments of the present inventions.

CLAIMS

1 1. A recombinant nucleic acid comprising a nucleic acid sequence
2 encoding Candida albicans TFIIB.

1 2. A vector comprising a nucleic acid sequence encoding Candida
2 albicans TFIIB.

1 3. A transformed host cell containing a nucleic acid sequence encoding
2 Candida albicans TFIIB.

1 4. A recombinant polypeptide comprising Candida albicans TFIIB.

1 5. A fragment of Candida albicans TFIIB, said fragment being
2 characterized in that it inhibits the biological activity of Candida albicans TFIIB in
3 transcription initiation.

1 6. A fragment of Candida albicans TFIIB, said fragment being
2 characterized in that it prevents the growth of Candida albicans.

1 7. A method for producing recombinant Candida albicans TFIIB,
2 comprising culturing the host cell of claim 3 under conditions sufficient to permit
3 expression of the nucleic acid encoding Candida albicans TFIIB, and isolating said
4 Candida albicans TFIIB.

1 8. A screening method for identifying an inhibitor of Candida albicans
2 growth, comprising detecting inhibition of mRNA transcription in an *in vitro* transcription
3 assay comprising a DNA template, RNA polymerase II, recombinant Candida albicans
4 TFIIB, and a candidate inhibitor, wherein production of an mRNA transcript from said
5 DNA template occurs in the absence if said candidate inhibitor.

1 9. A screening method for identifying an inhibitor of Candida albicans
2 growth, comprising detecting in the presence of a candidate inhibitor inhibition of
3 formation of a complex comprising a DNA template and recombinant Candida albicans
4 TFIIB, wherein in the absence of said candidate inhibitor, formation of said complex
5 occurs.

1 10. A screening method for identifying an inhibitor of *Candida albicans*
2 growth, comprising detecting in the presence of a candidate inhibitor inhibition of
3 formation of a complex comprising *Candida albicans* TFIIB and *Candida albicans* TBP,
4 wherein in the absence of said candidate inhibitor formation of said complex occurs.

1 11. A screening method for identifying an inhibitor of Candida albicans
2 growth, comprising detecting in the presence of a candidate inhibitor inhibition of
3 formation of a complex comprising RNA polymerase II, Candida albicans TBP, and
4 Candida albicans TFIIB, wherein in the absence of said candidate inhibitor formation of
5 said complex occurs.

1 12. The screening method of claim 8, 9, 10 or 11, wherein said
2 detecting is performed in the presence of a plurality of candidate inhibitors such that said
3 inhibition is indicative of inhibition by a said candidate inhibitor of said plurality.

1 13. The screening method of claim 8, 9, 10, or 11, wherein multiple
2 detecting steps are performed simultaneously using a plurality of candidate inhibitors,
3 wherein detection of inhibition by any one candidate inhibitor is detectable independently
4 of said plurality.

1 14. A method of preventing *Candida albicans* growth in culture,
2 comprising contacting said culture with an inhibitor that selectively inhibits the biological
3 activity of *Candida albicans* TFIIB.

1 15. A method of preventing *Candida albicans* growth in a mammal,
2 comprising contacting said mammal with an inhibitor that selectively inhibits the biological
3 activity of *Candida albicans* TFIIB.

SUBSTITUTE SHEET (RULE 26)

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US97/06171

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) :Please See Extra Sheet.

US CL :Please See Extra Sheet.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 536/23.1, 23.74; 435/320.1, 252.3, 325, 172.3, 69.1, 6, 7.1; 530/350, 300; 514/2

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, DIALOG - Biotech Files

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	KHOO et al. Conserved functional domains of the RNA polymerase III general transcription factor BRF. Genes and Development. 1994, Vol. 8, pages 2879-2890, see entire document.	1-15
Y	NA et al. The Kluyveromyces gene encoding the general transcription factor IIB: structural analysis and expression in <i>Saccharomyces cerevisiae</i> . Nucleic Acids Research. 1993, Vol. 21, No. 15, pages 3413-3417, see entire document.	1-15

Further documents are listed in the continuation of Box C. See patent family annex.

* Special categories of cited documents:	"T"	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
A document defining the general state of the art which is not considered to be of particular relevance	"X"	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
E earlier document published on or after the international filing date	"Y"	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reasons (as specified)	"g"	document member of the same patent family
O document referring to an oral disclosure, use, exhibition or other means		
P document published prior to the international filing date but later than the priority date claimed		

Date of the actual completion of the international search
